Question: Pat McGovern:

“Ben, I’m kind of curious – you know, your findings of the importance of self-efficacy in your model in addition to some of your other predictors – can you say a little bit more about what that construct really is, and how you impact it if you want to do that with a group of workers?”
Q&A

“Good afternoon, Dr. McGovern and the panel. My name is Rosalyn Wade. I’m the Assistant Commissioner at the Department of Labor and Industry. I was the individual that drug Peter kickin’ and screamin’ into the Ergonomics Task Force...”
“Hi, I’m Rosamund Schooner from the University of the Philippines. The comment is addressed to the main speaker. I’m very much appreciative of what you did on this quantification that you did in your study, because one of the big limitations in epi studies is the quantification of exposures and the outcomes. So I hope that you would give us details of where you’re going, if you have published or not published your work.

You also showed in your one graph where it pertained to chair comfort, right? And then you did show that for the control group, after the intervention there was an increased proportion of those who experienced chair comfort, right? And then – was that correct?

And then you said that you could not explain it. So I was thinking whether or not there was some spillover effect in terms of trainings or if, for example, the subjects that you have come from the same place, and there could be some spillover effect in terms of the content of the training. Then that could possibly explain an increase in the chair comfort after the intervention.”
